Why the report cites it

The study compares speech descriptions, gaze, and pointing as ways to reference objects while working with an intelligent assistant in VR. Its 39-participant evaluation reports task time, prompt counts, NASA-TLX, and UEQ outcomes. Gaze performed competitively while requiring little explicit user action, which supports treating gaze as contextual input for assistance rather than only as a selection method.

Limits on transfer

This paper supports gaze as an efficient referential signal. It does not validate the Gaze Contingency project's dwell threshold, hint timing, object layout, or gaze-classification rules. Those parameters still require headset-specific pilot testing.
